Abstract — Polychlorinated pollutants, such as polychlorinated biphenyls (PCBs) and polychlorinated dibenzo-p-dioxins/furans (PCDD/Fs), are toxic compounds generated during the incomplete combustion of agricultural plastics. This study investigates the characterization and emission patterns of these pollutants through controlled combustion experiments. By analyzing the combustion residues and emissions, the study identifies the major chemical species, evaluates their toxic equivalency, and explores the influence of variables such as temperature, plastic type, and oxygen levels. The findings highlight the significant environmental and health risks posed by agricultural plastic combustion and emphasize the need for better waste management practices to mitigate pollutant release.

Keywords— Polychlorinated pollutants, agricultural plastics, combustion, dioxins, PCBs, environmental pollution, toxic equivalency, waste management.

Introduction

Agricultural plastics, such as mulching films, greenhouse covers, and irrigation pipes, have become indispensable in modern farming due to their role in enhancing productivity and resource efficiency. However, improper disposal practices, particularly open burning, have raised significant environmental and health concerns. The combustion of these plastics, especially those containing chlorine, leads to the release of polychlorinated pollutants, including polychlorinated biphenyls (PCBs) and polychlorinated dibenzo-p-dioxins/furans (PCDD/Fs). These pollutants are highly toxic, persistent in the environment, and prone to bioaccumulation, posing severe risks to ecosystems and human health.

Despite increasing awareness of these hazards, comprehensive studies characterizing the pollutants generated from agricultural plastic burning remain scarce.

Understanding the chemical composition, emission patterns, and factors influencing pollutant formation is essential for developing effective mitigation strategies. This study aims to fill this knowledge gap by conducting a detailed analysis of polychlorinated pollutants emitted during the combustion of agricultural plastics under controlled conditions. The findings are expected to contribute to better waste management practices and policies, reducing the environmental footprint of agricultural plastics.

Literature Review

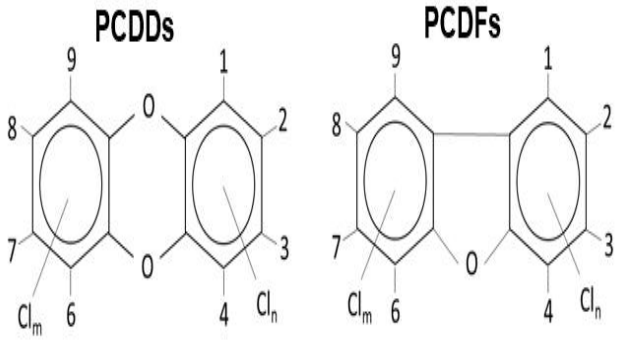

The improper disposal of agricultural plastics has become a growing environmental concern, particularly in regions where open burning is a common practice. This section reviews existing studies on the use, disposal, and environmental implications of agricultural plastics, focusing on the formation and impact of polychlorinated pollutants.

Agricultural Plastics: Usage and Disposal Practices

Agricultural plastics, including polyethylene (PE), polyvinyl chloride (PVC), and polypropylene (PP), play a crucial role in modern farming for mulching, greenhouse construction, and water conservation. However, their disposal poses significant challenges, as they are often discarded in landfills or openly burned in the absence of recycling facilities. A study by **Kyrikou and Briassoulis (2007)** emphasized that improper disposal, especially open-field burning, is a major source of environmental pollution, contributing to air, soil, and water contamination.

Formation of Polychlorinated Pollutants

Combustion of plastics, particularly those containing chlorine, results in the formation of harmful compounds such as polychlorinated biphenyls (PCBs) and polychlorinated dibenzo-p-dioxins/furans (PCDD/Fs). **Weber et al. (2008)** demonstrated that these compounds are primarily produced during incomplete combustion processes. Factors such as temperature, oxygen levels, and the chemical composition of plastics significantly influence pollutant formation. PVC, for instance, is a major contributor due to its high chlorine content.

Environmental and Health Impacts

Polychlorinated pollutants are highly toxic, with long-term effects on both ecosystems and human health. These compounds are classified as persistent organic pollutants (POPs) under the Stockholm Convention due to their ability to persist in the environment, bioaccumulate in food chains, and cause adverse health effects, including cancer and endocrine disruption. **Li et al. (2017)** reported that exposure to polychlorinated pollutants is associated with developmental disorders and immune system suppression, highlighting the need for stricter regulations on plastic waste management.

Analytical Methods for Pollutant Characterization

Advancements in analytical techniques have enabled better identification and quantification of polychlorinated pollutants. Gas chromatography-mass spectrometry (GC-MS) is widely used for detecting and analyzing trace levels of PCBs and PCDD/Fs. Studies such as **Choi et al. (2019)** emphasize the importance of using high-resolution analytical methods to assess the toxicity and environmental impact of emissions from plastic combustion.

Gaps in Research

While considerable research exists on the general impact of plastic waste, studies focusing specifically on the combustion of agricultural plastics remain limited. There is a need for

https://jiits.org/

more targeted investigations into the conditions that promote the formation of polychlorinated pollutants and their relative toxicities. Additionally, more attention is required to explore sustainable alternatives to current disposal practices.

Methodology

1. **Sample Collection and Preparation:** Agricultural plastics (e.g., polyethylene, PVC) were sourced from farms and cleaned to remove external contaminants.
2. **Combustion Setup:** A laboratory-scale combustion chamber was used to simulate open-burning conditions. Variables such as temperature (300–900°C), oxygen levels, and plastic types were systematically varied.
3. **Emission Sampling and Analysis:** Emissions were captured using high-efficiency particulate air (HEPA) filters and solvent traps. Gas chromatography-mass spectrometry (GC-MS) was employed to identify and quantify polychlorinated compounds.
4. **Residue Analysis:** Combustion residues were analyzed using X-ray fluorescence (XRF) spectroscopy to assess residual chlorine content.
5. **Toxicity Assessment:** Toxic equivalency factors (TEFs) were applied to evaluate the relative toxicity of the emissions.

Results

- **Pollutant Composition:** Significant levels of PCDD/Fs and PCBs were detected in the emissions, with higher concentrations observed at temperatures above 600°C.
- **Impact of Plastic Type:** PVC generated the highest levels of chlorinated pollutants due to its high chlorine content.
- **Oxygen Dependency:** Pollutant formation increased under low-oxygen conditions, highlighting the role of incomplete combustion.
- **Toxicity Evaluation:** Toxic equivalency analysis revealed emission profiles with high toxic potential, exceeding safety thresholds for ambient air quality.

Conclusion

The combustion of agricultural plastics, particularly those containing chlorine, generates significant quantities of hazardous polychlorinated pollutants such as polychlorinated biphenyls (PCBs) and polychlorinated dibenzo-p-dioxins/furans (PCDD/Fs). These pollutants pose substantial risks to human health and the environment due to their toxicity, persistence, and potential to bioaccumulate. This study highlights the critical factors influencing pollutant formation, including the type of plastic, combustion temperature, and oxygen availability. The findings demonstrate the urgent need for sustainable disposal methods, such as recycling or controlled incineration, to minimize the release of these harmful compounds.

Effective waste management policies and practices are essential to address the environmental challenges posed by agricultural plastic waste. Encouraging the use of biodegradable alternatives, improving recycling infrastructure, and promoting awareness among farmers can play a vital role in reducing open-burning practices. By addressing these issues, it is possible to mitigate the environmental and health impacts of agricultural plastic waste and contribute to a more sustainable agricultural system.

Scope and Limitations

Journal of Intelligent Internet of Things Systems (JIITS)
ISSN (Online): 3144-5160
Volume-2 Issue-2 || Apr – Jun 2025 || PP. 17 – 21
https://jiits.org/

Scope:

- Focuses on the characterization of polychlorinated pollutants under controlled combustion conditions.
- Provides insights into the impact of variables such as temperature, oxygen levels, and plastic composition.
- Offers recommendations for sustainable agricultural plastic disposal practices.

Limitations:

- The study is limited to laboratory-scale conditions, which may not fully represent open-field burning scenarios.
- The influence of environmental factors (e.g., wind, moisture) on pollutant formation was not assessed.
- Analysis was confined to a specific set of plastics; broader inclusion of other polymers could enhance applicability.
